Guide 8 — Responsive Design & Accessibility, the simple version

How Mobile Match Algeria adapts to different screen sizes and to three languages, in plain words — with the research, what is actually built, and an **honest list of the gaps** (so you can answer the jury, including on what is *not* finished).

1. The idea, in three sentences

The app should be usable on a phone, a tablet, or a desktop, and in French, English, or Arabic. It does this with **fluid layouts** that reflow as the screen narrows, a **mobile menu**, and full **trilingual support including right-to-left Arabic**, plus **accessibility basics** (labels for screen readers, semantic buttons, a light/dark theme). It is tuned first for desktop, and finer phone/tablet polish is openly listed as future work.

2. Responsive design — how it works

- **Fluid grids**: the card grids use `auto-fit / minmax`, so the number of columns adjusts itself to the window width — wide screen shows several cards per row, narrow screen shows fewer, automatically.
- **A breakpoint at 768 px**: below that width, the offers grid collapses to a **single column** and the page/section titles shrink, so cards are readable on a phone.
- **A mobile menu**: the navbar collapses into a **hamburger menu** on small screens instead of the full horizontal bar.
- **Device-width viewport**: the page scales to the device, so there is no tiny zoomed-out desktop layout on a phone.

Honest limit: the interface is tuned primarily for desktop. It adapts to phones for the main flows (browsing, the menu), but finer polish — especially the **comparison page on narrow screens** and tighter breakpoints for very small phones — is listed as **future work** in the thesis Perspectives, not claimed as finished.

3. Three languages, including right-to-left

- The whole interface is translated into **French, English, and Arabic** (one dictionary, `i18n.ts`).
- Selecting **Arabic flips the entire page to right-to-left**: the code sets `document.documentElement.dir = 'rtl'`, so text aligns right, rows reverse, and arrows flip direction. French and English stay left-to-right.

- The language choice is remembered between visits.

This matters for Algeria specifically, where Arabic is essential for reaching the full user base — and RTL is the part of internationalisation people most often get wrong, so having it work end-to-end is a real strength.

4. Accessibility basics

- **Labels for icon-only buttons:** buttons that show only an icon (clear search, help, dismiss) carry an `aria-label` so a screen reader announces what they do.
- **Live region:** the toast/notification area is an `aria-live="polite"` region, so screen readers read out confirmations and errors when they appear.
- **Semantic, keyboard-operable controls:** real `<button>` elements (not clickable divs), so they are focusable and usable with the keyboard.
- **Light / dark theme** and reasonable colour contrast.

Honest limit: these are the *basics*, not a full WCAG 2.2 audit. A complete pass (full focus management, an `aria-label` on every control, a formal contrast check) is future work.

5. Where each part comes from (the research)

Part	What it does	Comes from
Fluid grids + a media-query breakpoint	one layout that adapts to any width	Responsive Web Design (Marcotte, 2011): fluid grids, flexible media, and media queries
Labels, live regions, semantic controls	usable with assistive technology	WCAG 2.2 accessibility guidelines (perceivable, operable, understandable, robust)

What is *ours* is the configuration: which grids are fluid, the 768 px breakpoint, the hamburger menu, the trilingual dictionary, and the RTL switch.

6. What is done vs. what is future work (the honest summary)

Area	Done	Future work
Layout reflow	fluid grids, single-column at ≤768 px, mobile menu	tighter polish below 768 px; the comparison page on narrow phones
Languages	FR / EN / AR, full RTL for Arabic	—
Accessibility	aria-labels on icon buttons, aria-live toasts, semantic buttons, theme	full WCAG 2.2 audit (complete focus management, contrast checks)

Saying this plainly is a strength at the defense: you show you know both what works and what you would do next.

7. The files

- [globals.css](#) — the fluid grids and the 768 px breakpoint (single-column offers, smaller titles).
 - [components/navbar.tsx](#) — the hamburger mobile menu.
 - [lib/lang-context.tsx](#) — sets the language and flips `dir` to RTL for Arabic.
 - [lib/i18n.ts](#) — the FR / EN / AR dictionary.
 - [components/toast.tsx](#) — the aria-live notification region.
-

8. Jury questions — ready answers

- **Is it fully responsive?** It is responsive for the main flows: the grids reflow, the offers list becomes a single column on phones, and the navbar becomes a mobile menu. It is tuned first for desktop, and finer phone/tablet polish (the comparison page especially) is listed as future work — I am not claiming pixel-perfect on every device.
 - **Is it accessible?** The basics are in place: screen-reader labels on icon buttons, a live region for alerts, semantic keyboard-operable controls, and a theme. A full WCAG 2.2 audit is future work.
 - **How do you support Arabic?** The whole UI is translated, and choosing Arabic switches the document to right-to-left, so the layout mirrors correctly — not just the text.
 - **Why desktop-first?** The comparison and recommendation tables are information-dense and were easiest to get right on desktop first; the responsive reflow then covers smaller screens, with polish identified as the next step.
-

This completes the core-concept guide set (web scraping, recommendation, search, class diagram, notifications, comparison & savings, web data aggregation, responsive & accessibility).
